## The Alòs Itô decomposition formula

Following Elisa Alòs in [Alò12], let  $X_t = \log S_t/K$  and consider the price process

$$dX_t = \sigma_t \, dZ_t - \frac{1}{2} \, \sigma_t^2 \, dt.$$

Now let H(x, w) be some function that solves the Black-Scholes equation.

• Specifically,

$$-\partial_w H(x,w) + \frac{1}{2} (\partial_{xx} - \partial_x) H(x,w) = 0$$

which is of course the gamma-vega relationship.

Note in particular that ∂<sub>x</sub> and ∂<sub>w</sub> commute when applied to a solution of the Black-Scholes equation.

Decomposition	Trees and forests	Exponentiation	Rough Heston
0000000000000		0000000000	०००००००००००००००००

Now, define  $w_t(T)$  as the integral of the expected future variance:

$$w_t(T) := \mathbb{E}\left[\int_t^T \sigma_s^2 ds \middle| \mathcal{F}_t\right].$$

Notice that

$$w_t(T) = M_t - \int_0^t \sigma_s^2 ds,$$

where the martingale  $M_t := \mathbb{E}\left[ \left| \int_0^T \sigma_s^2 ds \right| \mathcal{F}_t \right]$ . Then it follows that

$$dw_t(T) = -\sigma_t^2 \, dt + dM_t.$$

0000000000000		0000000000	000000000000000000000000000000000000

Applying Itô's Lemma to  $H_t := H(X_t, w_t(T))$ , taking conditional expectations, simplifying using the Black-Scholes equation and integrating, we obtain

Theorem (The Itô Decomposition Formula of Alòs)

$$\mathbb{E}[H_T | \mathcal{F}_t] = H_t + \mathbb{E}\left[\int_t^T \partial_{xw} H_s d\langle X, M \rangle_s \middle| \mathcal{F}_t\right] \\ + \frac{1}{2} \mathbb{E}\left[\int_t^T \partial_{ww} H_s d\langle M, M \rangle_s \middle| \mathcal{F}_t\right].$$
(1)

• Note in particular that (1) is an *exact* decomposition.

Decomposition	Trees and forests	Exponentiation	Rough Heston
0000000000000		00000000000	000000000000000000000000000000000000

# Freezing derivatives

Freezing the derivatives in the Alòs Itô decomposition formula (1) gives us the approximation

$$\mathbb{E}[H_T|\mathcal{F}_t] \approx H_t + \mathbb{E}\left[\int_t^T d\langle X, M \rangle_s \middle| \mathcal{F}_t\right] \partial_{xw} H_t \\ + \frac{1}{2} \mathbb{E}\left[\int_t^T d\langle M, M \rangle_s \middle| \mathcal{F}_t\right] \partial_{ww} H_t \\ = H_t + (X \diamond M)_t(T) \cdot H_t + \frac{1}{2}(M \diamond M)_t(T) \cdot H_t.$$

#### Remark

The essence of the Exponentiation Theorem is that we may express  $\mathbb{E}[H_T | \mathcal{F}_t]$  as an exact expansion consisting of infinitely many terms, with derivatives in each such term frozen.

# Diamond and dot notation

Let  $A_t$  and  $B_t$  be semimartingales (here some combinations of X and M). Then

$$(A\diamond B)_t(T) = \mathbb{E}\left[\int_t^T d\langle A, B\rangle_s \middle| \mathcal{F}_t\right].$$

When  $(A \diamond B)_t(T)$  appears before some solution  $H_t$  of the Black-Scholes equation, the dot  $\cdot$  is to be understood as representing the action of  $\partial_x$  and  $\partial_w$  applied to  $H_t$ .

So for example

$$(X \diamond M)_t(T) \cdot H_t = \mathbb{E}\left[\int_t^T d\langle X, M \rangle_s \middle| \mathcal{F}_t\right] \partial_{xw} H_t$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

and so on.

Exponentiation 000000000

Rough Heston

# Diamond functionals as covariances

• Diamond (or autocovariance) functionals are intimately related to conventional covariances.

#### Lemma

Let A and B be martingales in the same filtered probability space. Then

$$(A \diamond B)_t(T) = \mathbb{E}\left[A_T B_T | \mathcal{F}_t\right] - A_t B_t = \operatorname{cov}\left[A_T, B_T | \mathcal{F}_t\right].$$

 By finding the appropriate martingales, it is thus always possible to re-express autocovariance functionals in terms of covariances of terminal quantities. For example, it is easy to show that (M ◊ M)<sub>t</sub>(T) = var [⟨X⟩<sub>T</sub> | F<sub>t</sub>]. Decomposition 000000000000000 Trees and forests

Exponentiation 000000000

# Autocovariance functionals vs covariances

- Covariances are typically easy to compute using simulation.
- Diamond functionals are expressible directly in terms of the formulation of a model in forward variance form.

Trees and forests

Exponentiation 000000000

Rough Heston

# Conditional variance of $X_T$

Consider

$$F_t = X_t^2 + w_t(T)(1 - X_t) + \frac{1}{4}w_t(T)^2.$$

F(x, w) satisfies the Black-Scholes equation and F<sub>T</sub> = X<sup>2</sup><sub>T</sub>.
∂<sub>x,w</sub>F = −1 and ∂<sub>w,w</sub>F = <sup>1</sup>/<sub>2</sub>.

• Plugging into the Decomposition Formula (1) gives

$$\mathbb{E}\left[X_{T}^{2}\middle|\mathcal{F}_{t}\right] = w_{t}(T) + \frac{1}{4}w_{t}(T)^{2} - \mathbb{E}\left[\int_{t}^{T}d\langle X, M\rangle_{s}\middle|\mathcal{F}_{t}\right] \\ + \frac{1}{4}\mathbb{E}\left[\int_{t}^{T}d\langle M, M\rangle_{s}\middle|\mathcal{F}_{t}\right] \\ = w_{t}(T) + \frac{1}{4}w_{t}(T)^{2} \\ -(X \diamond M)_{t}(T) + \frac{1}{4}(M \diamond M)_{t}(T).$$

Trees and forests

Exponentiation 0000000000 Rough Heston

# Volatility stochasticity

#### We can rewrite this as

Lemma

$$\zeta_t(T) := \operatorname{var}[X_T | \mathcal{F}_t] - w_t(T) = -(X \diamond M)_t(T) + \frac{1}{4} (M \diamond M)_t(T).$$

- Recall that in a stochastic volatility model, the variance of the terminal distribution of the log-underlying is not in general equal to the expected quadratic variation.
  - In the Black-Scholes model of course  $\zeta_t(T) = 0$ .
- We call the difference ζ<sub>t</sub>(T) volatility stochasticity or just stochasticity.

Decomposition 000000000000000	Trees and forests	Exponentiation 00000000000	Rough Heston
Model calibratio	n		

Once again, stochasticity is given by

$$\zeta_t(T) = -(X \diamond M)_t(T) + \frac{1}{4} (M \diamond M)_t(T).$$

- The LHS may be estimated from the volatility surface using the spanning formula.
  - $\zeta_t(T)$  is a tradable asset for each T.
  - We get a matching condition for each expiry  $T_i$ ,  $i \in \{1, ...n\}$ .
- The RHS may typically be computed in a given model as a function of model parameters.
  - If so, we would be able to calibrate such a model directly to tradable assets with no need for any expansion.

Trees and forests

Exponentiation

Rough Heston

# $\zeta_t(T)$ directly from the smile

Let

$$d_{\pm}(k) = rac{-k}{\sigma_{\mathrm{BS}}(k,T)\sqrt{T}} \pm rac{\sigma_{\mathrm{BS}}(k,T)\sqrt{T}}{2}$$

and following Fukasawa, denote the inverse functions by  $g_{\pm}(z) = d_{\pm}^{-1}(z)$ . Further define

$$\sigma_{-}(z) = \sigma_{\rm BS}(g_{-}(z), T) \sqrt{T}.$$

<b>00000000000000</b> 00000000 0000000000000	Decomposition	Trees and forests	Exponentiation	Rough Heston
	000000000000000000000000000000000000000	0000000	0000000000	000000000000000000000000000000000000000

In terms of the implied volatility smile, it is a well-known corollary of Matytsin's characteristic function representation in [Mat00], that

$$w_t(T) = \int dz \, N'(z) \, \sigma_-^2(z) =: \bar{\sigma}^2.$$

Similarly, we can show that

$$\zeta_t(T) = \frac{1}{4} \int N'(z) \, \left[\sigma_-^2(z) - \bar{\sigma}^2\right]^2 \, dz + \frac{2}{3} \int N'(z) \, z \, \sigma_-^3(z) \, dz.$$

- We may thus in principle use stochasticity to calibrate any given model.
  - In practice, we need a good parameterization of the implied volatility surface (see VolaDynamics later).
  - Whether or not market implied stochasticity is robust to the interpolation and extrapolation method is still to be explored.

### Forward variance models

Following [BG12], consider the model

$$\frac{dS_t}{S_t} = \sqrt{v_t} \left\{ \rho \, dW_t + \sqrt{1 - \rho^2} \, dW_t^\perp \right\}$$
$$d\xi_t(u) = \lambda(t, u, \xi_t) \, dW_t. \tag{2}$$

where  $v_t = \sigma_t^2$  denotes instantaneous variance and the  $\xi_t(u) = \mathbb{E}[v_u | \mathcal{F}_t], u \in [t, T]$  are forward variances.

 To expand such a model, we scale the volatility of volatility function λ(·) so that λ → ε λ. Setting ε = 1 at the end then gives the required expansion. Decomposition 00000000000000000 Trees and forests

Decomposition

Trees and forests 00000000 Exponentiation •••••••• Rough Heston

# The Exponentiation Theorem

The following theorem proved in [AGR2017] follows from (more or less) a simple application of Itô's Lemma and the Alòs Itô decomposition formula.

#### Theorem

Let  $H_t$  be any solution of the Black-Scholes equation such that  $\mathbb{E}[H_T | \mathcal{F}_t]$  is finite and the integrals contributing to each forest  $\mathbb{F}_k, k \ge 0$  exist. Then

$$\mathbb{E}\left[\left.H_{T}\right|\mathcal{F}_{t}\right]=e^{\sum_{k=1}^{\infty}\mathbb{F}_{k}}\cdot H_{t}.$$

Decomposition 000000000000000 Trees and forests

Exponentiation 0000000000 Rough Heston

# If $H_t$ is a characteristic function

Consider the Black-Scholes characteristic function

$$\Phi_t^T(a) = e^{\mathrm{i} a X_t - \frac{1}{2}a(a+\mathrm{i})w_t(T)}$$

which satisfies the Black-Scholes equation.

- Applying 𝔽<sub>k</sub> to Φ just multiplies Φ by some deterministic factor.
- Then

$$e^{\sum_{k=1}^{\infty} \mathbb{F}_k} \cdot \Phi_t^{\mathsf{T}}(a) = e^{\sum_{k=1}^{\infty} \widetilde{\mathbb{F}}_k(a)} \Phi_t^{\mathsf{T}}(a)$$

where  $\tilde{\mathbb{F}}_k(a)$  is  $\mathbb{F}_k$  with each occurrence of  $\partial_x$  replaced with i *a* and each occurrence of  $\partial_w$  replaced with  $-\frac{1}{2}a(a+i)$ .

Decomposition	Trees and forests	Exponentiation	Rough Heston
0000000000000		0000000000	000000000000000000000000000000000000

# Then from the Exponentiation Theorem, we have the following lemma.

#### Lemma

Let

$$\varphi_t^{\mathsf{T}}(\mathsf{a}) = \mathbb{E}\left[\left. e^{i\,\mathsf{a}\,\mathsf{X}_{\mathsf{T}}} \right| \mathcal{F}_t 
ight]$$

be the characteristic function of the log stock price. Then

$$\varphi_t^{\mathsf{T}}(a) = e^{\sum_{k=1}^{\infty} \tilde{\mathbb{F}}_k(a)} \Phi_t^{\mathsf{T}}(a).$$

#### Corollary

The cumulant generating function (CGF) is given by

$$\psi_t^T(a) = \log \varphi_t^T(a) = \mathrm{i} \, a \, X_t - \frac{1}{2} a \, (a + \mathrm{i}) \, w_t(T) + \sum_{k=1}^{\infty} \tilde{\mathbb{F}}_k(a).$$

Decomposition	Trees and forests	Exponentiation	Rough Heston
00000000000000		0000000000	0000000000000000000

### Variance and gamma swaps

The variance swap is given by the fair value of the log-strip:

$$\mathbb{E}\left[X_{T}|\mathcal{F}_{t}\right] = (-\mathrm{i})\psi_{t}^{T'}(0) = X_{t} - \frac{1}{2}w_{t}(T)$$

and the gamma swap (wlog set  $X_t = 0$ ) by

$$\mathbb{E}\left[X_{T} e^{X_{T}} \middle| \mathcal{F}_{t}\right] = -\mathrm{i} \psi_{t}^{T'}(-\mathrm{i}).$$

#### Remark

The point is that we can in principle compute such moments for any stochastic volatility model written in forward variance form, whether or not there exists a closed-form expression for the characteristic function.

Decomposition	Trees and forests	Exponentiation	Rough Heston
00000000000000		0000000000	00000000000000000000

### The gamma swap

It is easy to see that only trees containing a single M leaf will survive in the sum after differentiation when a = -i so that

$$\sum_{k=1}^{\infty} \tilde{\mathbb{F}}'_{k}(-\mathrm{i}) = \frac{\mathrm{i}}{2} \sum_{k=1}^{\infty} (X \diamond)^{k} M$$

where  $(X\diamond)^k M$  is defined recursively for k > 0 as  $(X\diamond)^k M = X\diamond (X\diamond)^{k-1}M$ . Then the fair value of a gamma swap is given by

$$\mathcal{G}_t(T) = 2 \mathbb{E} \left[ \left| X_T e^{X_T} \right| \mathcal{F}_t \right] = w_t(T) + \sum_{k=1}^{\infty} (X \diamond)^k M.$$
 (3)

#### Remark

Equation (3) allows for explicit computation of the gamma swap for any model written in forward variance form.

Decomposition	Trees and forests	Exponentiation	Rough Heston
00000000000000		0000000000	00000000000000000000

We deduce that the fair value of a leverage swap is given by

I he leverage swap

$$\mathcal{L}_t(T) = \mathcal{G}_t(T) - w_t(T) = \sum_{k=1}^{\infty} (X\diamond)^k M.$$
(4)

- The leverage swap is expressed explicitly in terms of covariance functionals of the spot and vol. processes.
  - If spot and vol. processes are uncorrelated, the fair value of the leverage swap is zero.

An explicit expression for the leverage swap!

# Skewness

As is well-known, the first three central moments are easily computed from cumulants by differentiation. For example, skewness is given by

$$S_{t}(T) := \mathbb{E}\left[\left(X_{T} - \bar{X}_{T}\right)^{3} \middle| \mathcal{F}_{t}\right]$$

$$= (-i)^{3} \psi_{t}^{T'''}(0)$$

$$= -\frac{3}{2} (M \diamond M)_{t}(T) - \frac{3}{8} (M \diamond (M \diamond M))_{t}(T)$$

$$+\frac{3}{2} (M \diamond (X \diamond M))_{t}(T) + 3 (X \diamond M)_{t}(T)$$

$$+\frac{3}{4} (X \diamond (M \diamond M))_{t}(T) - 3 (X \diamond (X \diamond M))_{t}(T).$$
(5)

ヘロト 人間 とくほと くほど

An explicit expression for skewness!

# The Bergomi-Guyon smile expansion

 The Bergomi-Guyon (BG) smile expansion (Equation (14) of [BG12]) reads

$$\sigma_{\rm BS}(k, T) = \hat{\sigma}_T + \mathcal{S}_T k + \mathcal{C}_T k^2 + \mathcal{O}(\epsilon^3)$$

where the coefficients  $\hat{\sigma}_T$ ,  $S_T$  and  $C_T$  are complicated combinations of trees such as  $X \diamond M$ .

• As we have seen, such trees are formally easily computable in any stochastic volatility model written in forward variance form.

• The beauty of the BG expansion is that in some sense, it yields direct relationships between the smile and autocovariance functionals.

Decomposition	Trees and forests	Exponentiation	Rough Heston
00000000000000		00000000000	000000000000000000000000000000000000

# Bergomi-Guyon to higher order

- We can extend the Bergomi-Guyon expansion to any desired order using our formal expression for the CGF in terms of forests.
- To second order, the ATM volatility skew is given by

$$\begin{aligned} \psi_t(T) &:= \partial_k \sigma_{\mathrm{BS}}(k,T)|_{k=0} \\ &= \sqrt{\frac{w}{T}} \left\{ \frac{1}{2w^2} \left( X \diamond M \right) + \frac{1}{2w^2} \left( X \diamond (X \diamond M) \right) - \frac{3}{8w^3} \left( X \diamond M \right)^2 \right\} \end{aligned}$$
(6)

• It seems to be more natural to consider the total implied variance skew. For example, to third order,

$$\begin{aligned} & = \frac{X \diamond M}{w} + \frac{X \diamond (X \diamond M)}{w} - \frac{1}{2} \left(\frac{X \diamond M}{w}\right)^2 + \frac{3}{4} \left(X \diamond (X \diamond (X \diamond M))\right) \frac{w - 4}{w^2} \\ & - (M \diamond (X \diamond M)) \frac{w + 12}{8w^2} - (X \diamond (M \diamond M)) \frac{w + 12}{16w^2} \\ & + (M \diamond M) \left(X \diamond M\right) \frac{w + 14}{8w^3} + (X \diamond M)^3 \frac{w - 64}{16w^4} - \frac{1}{2} \left(X \diamond M\right) \left(X \diamond (X \diamond M)\right) \frac{w - 14}{w^3} \end{aligned}$$

## Skewness, leverage, stochasticity and the volatility skew

- The explicit expression (5) for skewness applies to any stochastic volatility model written in forward variance form.
- There are numerous references in the literature to the connection between the implied volatility skew and both the skewness and the leverage swap.
- Our explicit expression shows how these three quantities are related.
  - Denoting the ATM implied volatility skew by  $\psi_t(T)$ , we have from the BG expansion that to lowest order,

$$\psi_t(T) = \sqrt{\frac{w}{T}} \frac{1}{2w^2} (X \diamond M)_t(T)$$

and to lowest order in the forest expansion,

$$\frac{1}{3}S_t(T) = (X \diamond M)_t(T) = \mathcal{L}_t(T) = -\zeta_t(T).$$

Exponentiation 00000000000

# The rough Heston model

In the zero mean reversion limit, the rough Heston model of [ER16] may be written as

$$\frac{dS_t}{S_t} = \sqrt{v_t} \left\{ \rho \, dW_t + \sqrt{1 - \rho^2} \, dW_t^{\perp} \right\} = \sqrt{v_t} \, dZ_t$$

with

$$v_u = \xi_t(u) + rac{
u}{\Gamma(\alpha)} \int_t^u rac{\sqrt{v_s}}{(u-s)^{\gamma}} dW_s, \quad u \ge t$$

where  $\xi_t(u) = \mathbb{E}[v_u | \mathcal{F}_t]$  is the forward variance curve,  $\gamma = \frac{1}{2} - H$ and  $\alpha = 1 - \gamma = H + \frac{1}{2}$ .

$$d\xi_t(u) = \frac{\nu}{\Gamma(\alpha)} \frac{\sqrt{v_t}}{(u-t)^{\gamma}} \, dW_t. \tag{7}$$

### Remark

(7) is a natural fractional generalization of the classical Heston model which reads, in forward variance form [BG12],

$$d\xi_t(u) = \nu \sqrt{v_t} e^{-\kappa (u-t)} dW_t.$$

Exponentiation

# Computation of autocovariance functionals

(

Apart from  $\mathcal{F}_t$  measurable terms (abbreviated as 'drift'), we have

$$dX_t = \sqrt{v_t} \, dZ_t + \text{drift}$$
  

$$dM_t = \int_t^T d\xi_t(u) \, du$$
  

$$= \frac{\nu}{\Gamma(\alpha)} \sqrt{v_t} \left( \int_t^T \frac{du}{(u-t)^{\gamma}} \right) \, dW_t$$
  

$$= \frac{\nu (T-t)^{\alpha}}{\Gamma(1+\alpha)} \sqrt{v_t} \, dW_t.$$

## The first order forest

There is only one tree in the forest  $\mathbb{F}_1$ .

$$\begin{split} \mathbb{F}_1 &= (X \diamond M)_t(T) &= \mathbb{E}\left[\int_t^T d\langle X, M \rangle_s \middle| \mathcal{F}_t\right] \\ &= \frac{\rho \nu}{\Gamma(1+\alpha)} \mathbb{E}\left[\int_t^T v_s \, (T-s)^\alpha \, ds \middle| \mathcal{F}_t\right] \\ &= \frac{\rho \nu}{\Gamma(1+\alpha)} \int_t^T \xi_t(s) \, (T-s)^\alpha \, ds. \end{split}$$

Trees and forest

Exponentiation 000000000

Rough Heston

# Higher order forests

Define for  $j \ge 0$ 

$$I_t^{(j)}(T) := \int_t^T ds \, \xi_t(s) \, (T-s)^{j\,lpha}.$$

Then

$$dl_{s}^{(j)}(T) = \int_{s}^{T} du \, d\xi_{s}(u) \, (T-u)^{j\,\alpha} + \text{ drift terms}$$
  
$$= \frac{\nu \sqrt{v_{s}}}{\Gamma(\alpha)} \, dW_{s} \int_{s}^{T} \frac{(T-u)^{j\,\alpha}}{(u-s)^{\gamma}} \, du + \text{ drift terms}$$
  
$$= \frac{\Gamma(1+j\,\alpha)}{\Gamma(1+(j+1)\,\alpha)} \, \nu \, \sqrt{v_{s}} \, (T-s)^{(j+1)\,\alpha} \, dW_{s} + \text{ drift terms.}$$

With this notation,

$$(X \diamond M)_t(T) = \frac{\rho \nu}{\Gamma(1+\alpha)} I_t^{(1)}(T).$$

Trees and forest

Exponentiation

Rough Heston

## The second order forest

There are two trees in  $\mathbb{F}_2$ :

$$(M \diamond M)_t(T) = \mathbb{E}\left[\int_t^T d\langle M, M \rangle_s \middle| \mathcal{F}_t\right]$$
  
=  $\frac{\nu^2}{\Gamma(1+\alpha)^2} \int_t^T \xi_t(s) (T-s)^{2\alpha} ds$   
=  $\frac{\nu^2}{\Gamma(1+\alpha)^2} I_t^{(2)}(T)$ 

and

$$\begin{aligned} (X \diamond (X \diamond M))_t (T) &= \left. \frac{\rho \nu}{\Gamma(1+\alpha)} \mathbb{E} \left[ \int_t^T d \langle X, I^{(1)} \rangle_s \right| \mathcal{F}_t \right] \\ &= \left. \frac{\rho^2 \nu^2}{\Gamma(1+2\alpha)} I_t^{(2)}(T). \end{aligned}$$

Exponentiation 000000000

Rough Heston

# The leverage swap under rough Heston

Using (4), we have

$$\mathcal{L}_{t}(T) = \sum_{k=1}^{\infty} (X \diamond)^{k} M_{t}(T)$$

$$= \sum_{k=1}^{\infty} \frac{(\rho \nu)^{k}}{\Gamma(1+k \alpha)} \int_{t}^{T} du \xi_{t}(u) (T-u)^{k \alpha}$$

$$= \int_{t}^{T} du \xi_{t}(u) \{E_{\alpha}(\rho \nu (T-u)^{\alpha}) - 1\}$$
(8)

where  $E_{\alpha}(\cdot)$  denotes the Mittag-Leffler function.

An explicit expression for the leverage swap!

Decomposition	Trees and forests	Exponentiation	Rough Heston
00000000000000		00000000000	00000000000000000000

## The normalized leverage swap

Given the form of equation (8), it is natural to normalize the leverage swap by the variance swap. We therefore define

$$L_t(T) = \frac{\mathcal{L}_t(T)}{w_t(T)}.$$
(9)

In the special case of the rough Heston model with a flat forward variance curve,

$$L_t(T) = E_{\alpha,2}(\rho \,\nu \,\tau^{\alpha}) - 1,$$

where  $E_{\alpha,2}(\cdot)$  is a generalized Mittag-Leffler function. We further define an *n*th order approximation to  $L_t(T)$  as

$$L_t^{(n)}(T) = \sum_{k=1}^n \frac{(\rho \,\nu \,\tau^\alpha)^k}{\Gamma(2+k\,\alpha)}.$$

Exponentiation

Rough Heston

# The leverage swap under rough Heston

We note that three terms are enough to get a very good approximation to the normalized leverage swap for all expirations traded in the listed market. Moreover, leverage swaps are straightforward to estimate from volatility smiles.

## Remark

In practice, (9) can be used for very fast and efficient calibration of the three parameters of the rough Heston model by minimizing the distance between model and empirical normalized leverage swap estimates.

Rough Heston

# Stochasticity under rough Heston

## Recall that

$$\zeta_t(T) = -X \diamond M + \frac{1}{4}(M \diamond M).$$

Under rough Heston, we easily compute

$$\zeta_t(T) = -\frac{\rho \nu}{\Gamma(1+\alpha)} I_t^{(1)}(T) + \frac{\nu^2}{\Gamma(1+\alpha)^2} I_t^{(2)}(T)$$

where

$$I_t^{(j)}(T) := \int_t^T ds \, \xi_t(s) \, (T-s)^{j\,\alpha}.$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ ─臣 ─ のへで

Decomposition 00000000000000	Trees and forests	Exponentiation 00000000000	Rough Heston

With a flat variance curve,

$$I_t^{(j)}(T) := \int_t^T \, ds \, \xi_t(s) \, (T-s)^{j \, \alpha} = \frac{w}{j \, \alpha + 1} \, (T-t)^{j \, \alpha}$$

where

$$w=\int_t^T \xi_t(s)\,ds.$$

Then

$$\frac{\zeta_t(T)}{w} = -\frac{\rho \nu}{\Gamma(2+\alpha)} (T-t)^{\alpha} + \frac{\nu^2}{(1+2\alpha)\Gamma(1+\alpha)^2} (T-t)^{2\alpha}.$$
