High-Energy Astrophysics

- Produced by multi-million degree matter, e.g., magnetic fields, extreme gravity, or explosive forces.
- Provide understanding into the hot turbulent regions of the universe.
- X-ray and γ -ray detectors typically count a *small number of photons* in each of a *large number of pixels*.

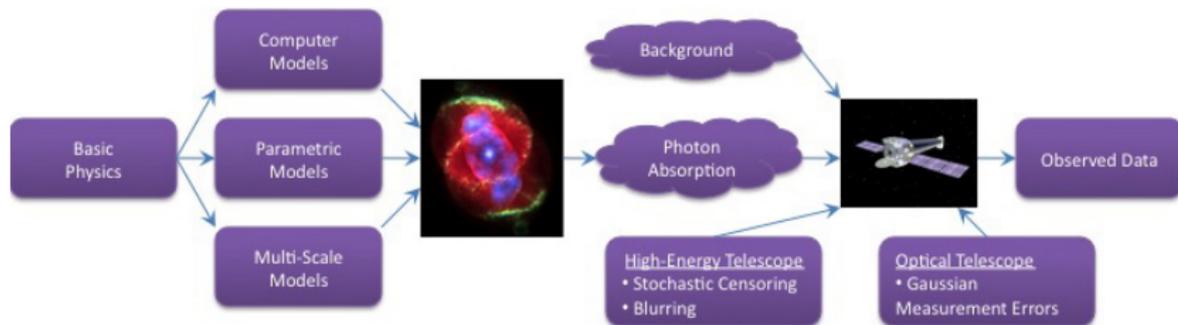

EGERT γ -ray counts $>1\text{GeV}$
(entire sky and mission life).

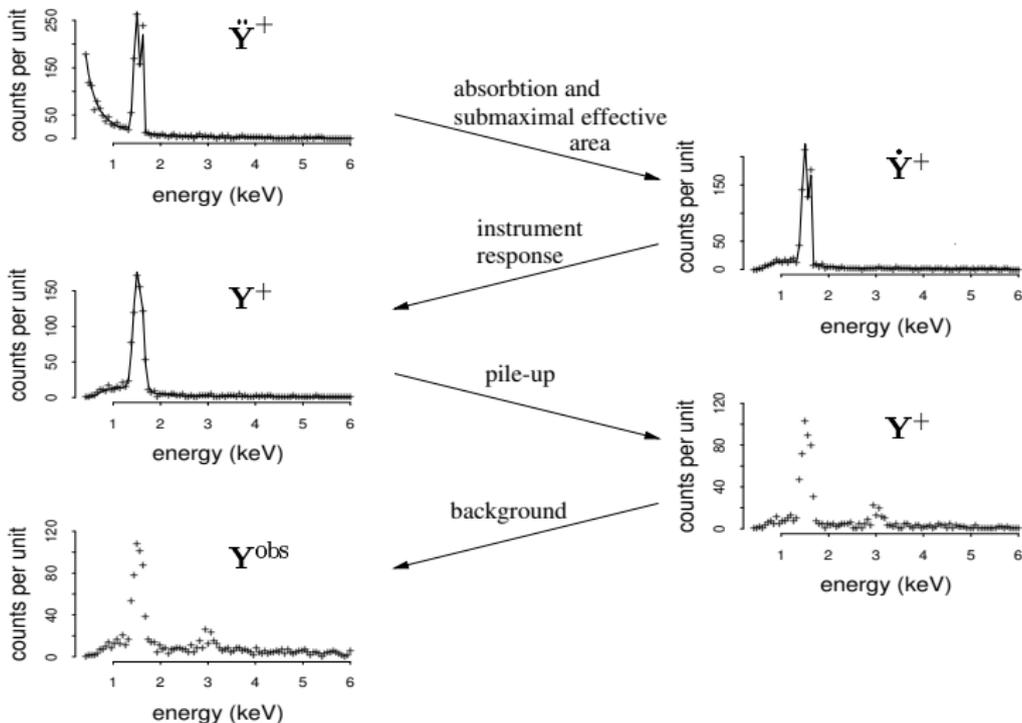

Dispersion grating spectrum of an Active Galactic Nucleus; emission from matter accreting onto a massive Black Hole.

The Basic Statistical Model

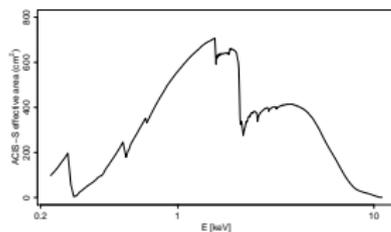

- Aim to formulate models in terms of specific questions of scientific interest.
- Must account for complexities of data generation.
- Embed complex physics-based and/or instrumental models into multi-level statistical models.
- State of the art data and computational techniques enable us to fit the resulting complex model.

Degradation of the Photon Counts

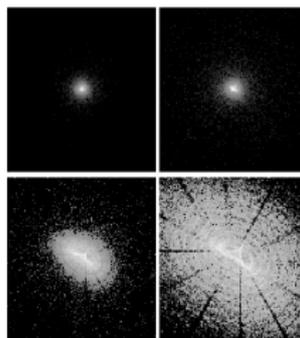

Calibration Products

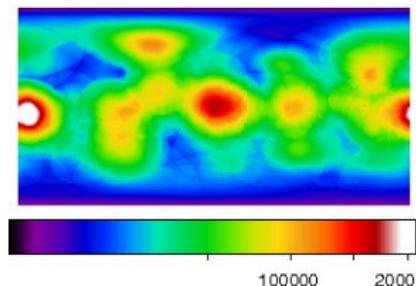

- Analysis is highly dependent on *Calibration Products*:
 - Effective area records sensitivity as a function of energy
 - Energy redistribution matrix can vary with energy/location
 - Point Spread Functions can vary with energy and location
 - Exposure Map shows how effective area varies in an image
- In this talk we focus on uncertainty in the effective area.

A CHANDRA effective area.

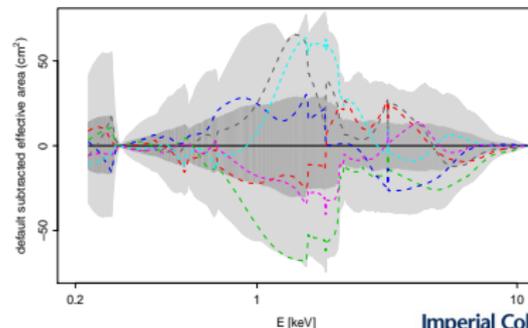

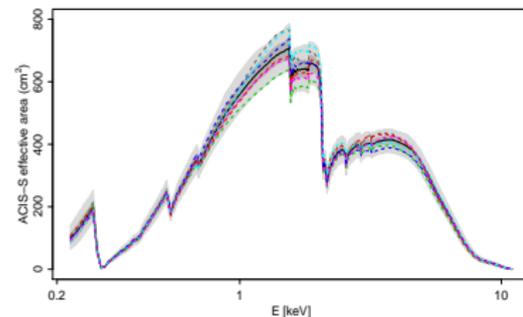

Sample Chandra psf's
 (Karovska et al., ADASS X)

EGERT exposure map
 (area \times time)

Derivation of Calibration Products

- Prelaunch ground-based and post-launch space-based empirical assessments.
- Aim to capture deterioration of detectors over time.
- Complex computer models of subassembly components.
- Calibration scientists provide a sample representing uncertainty
- *Calibration Sample* is typically of size ≈ 1000 .

Bayesian Statistical Analyses: Likelihood

Likelihood Functions: The distribution of the data given the model parameters. E.g., $Y \sim \text{Poisson}(\lambda_S)$:

$$\text{likelihood}(\lambda_S) = e^{-\lambda_S} \lambda_S^Y / Y!$$

Maximum Likelihood Estimation: Suppose $Y = 3$

The likelihood and its normal approximation.

Can estimate λ_S and its error bars.

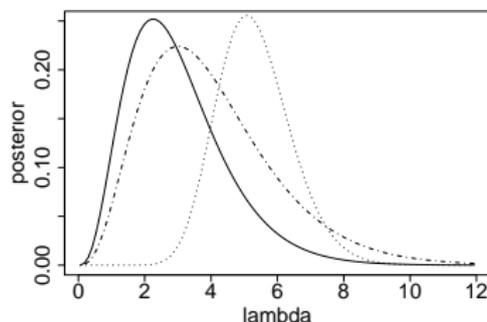

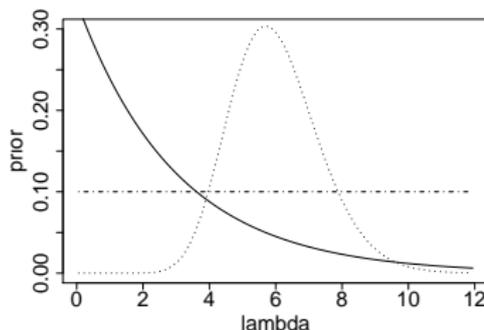

Bayesian Analyses: Prior and Posterior Dist'ns

Prior Distribution: Knowledge obtained *prior* to current data.

Bayes Theorem and Posterior Distribution:

$$\text{posterior}(\lambda) \propto \text{likelihood}(\lambda)\text{prior}(\lambda)$$

Combine past and current information:

Bayesian analyses allows us to incorporate external information via the prior distribution.

The Standard Approach

In high energy astrophysics the effective area curve is invariably assumed known:

$$p(\theta|A, Y) \propto p(Y|\theta, A)p(\theta|A).$$

θ : Model parameters, of primary scientific interest.

A : Effective area curve, typically assumed known.

Y : Observed data–bin counts.

*Treating A as known is a **very** strong prior!!*

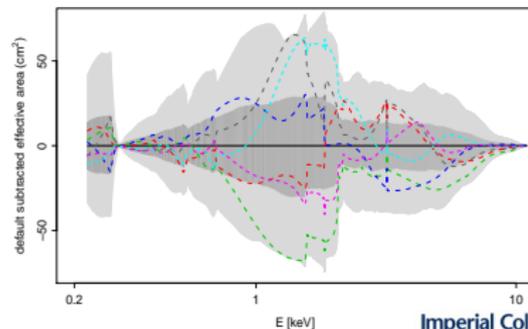

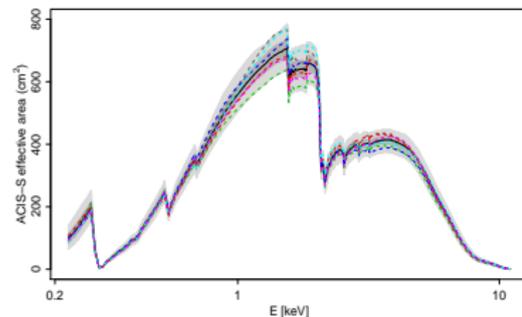

Our Approach

We

- introduce a Bayesian approach to **reduce** prior assumptions,
- propose to use the calibration sample to represent the prior distribution for A , and
- base analysis on:

$$p(\theta, A | Y) \propto p(Y | \theta, A) p(\theta | A) p(A).$$

$$p(\theta | Y) = \int p(\theta, A | Y) dA.$$

Two Possible Target Distributions

We consider inference under:

A PRAGMATIC BAYESIAN TARGET: $\pi_0(A, \theta) = p(A)p(\theta|A, Y)$.

THE FULLY BAYESIAN POSTERIOR: $\pi(A, \theta) = p(A|Y)p(\theta|A, Y)$.

Concerns:

Statistical Fully Bayesian target is “correct”.

Cultural Astronomers have concerns about letting the current data influence calibration products.

Computational Both targets pose challenges, but pragmatic Bayesian is easier to fit.

Practical How different are $p(A)$ and $p(A|Y)$?

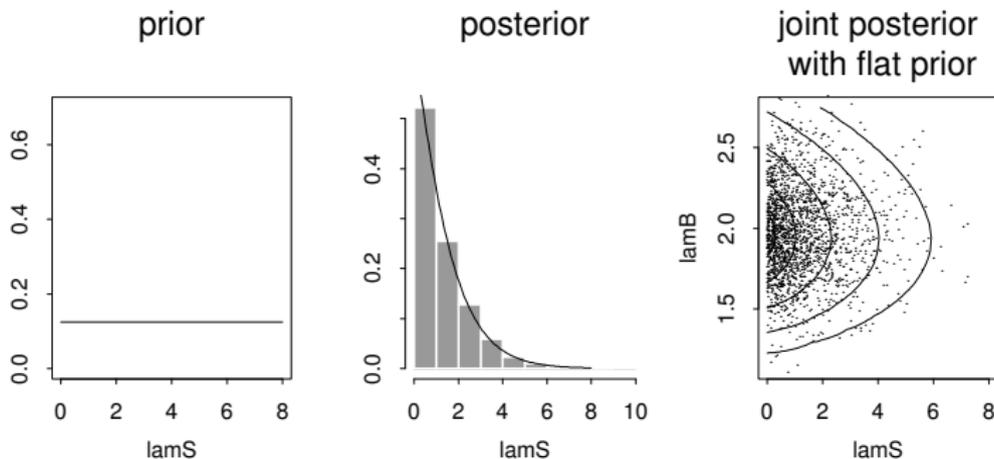

Model Fitting via Monte Carlo

Consider a contaminated Poisson count:

Source: $Y \sim \text{Poisson}(\lambda_s + \lambda_b)$

Background: $X \sim \text{Poisson}(c\lambda_b)$

Exploring the posterior distribution via Monte Carlo:

A Gibbs Sampler for Calibration Uncertainty

A Markov chain Monte Carlo sampler iterates:

Step 1: Sample the effective area curve given the current value of model parameters.

Step 2: Sample the model parameters given the current value of the effective area.

- Step 2 samples under standard approach.
- Step 1 swaps in a different effective area at each iteration.
- **Fully Bayes:** Step 1 samples $\pi(A|\theta)$.
- **Pragmatic Bayes:** $\pi_0(A)$ is easier to sample than $\pi_0(A|\theta)$.
- Both effectively average over calibration uncertainty.

MH within Partially Collapsed Gibbs Samplers

MCMC for Pragmatic Bayes

Step 1: Sample the effective area curve from $\pi_0(\mathbf{A})$.

Step 2: Sample the model parameters from $\pi_0(\theta|\mathbf{A})$.
This requires an MH update.

A *naive* Sampler:

STEP 1: $\psi_1 \sim p(\psi_1)$

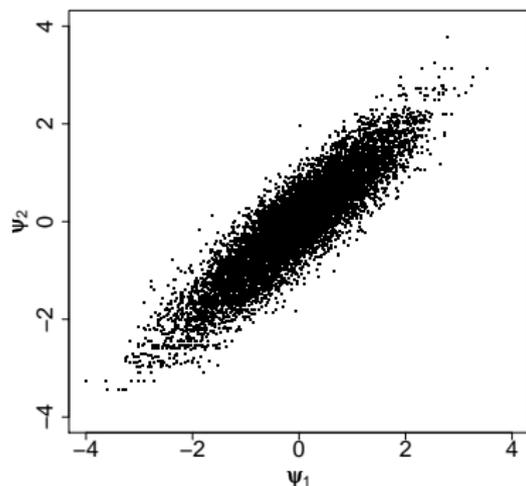

STEP 2: $\psi_2 \sim \mathcal{M}(\psi_2|\psi_1)$ via MH with limiting dist. $p(\psi_2|\psi_1)$

Simulation Study:

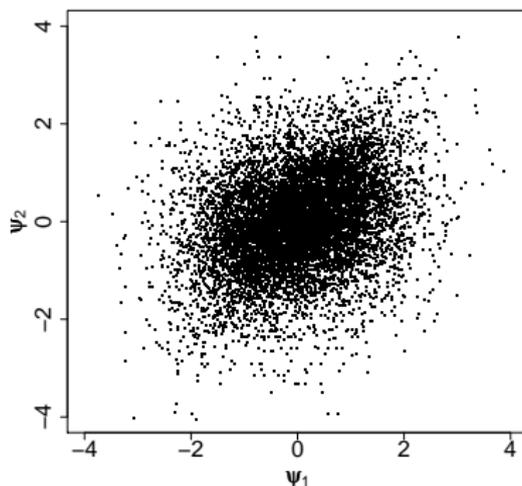

- Suppose $\begin{pmatrix} \psi_1 \\ \psi_2 \end{pmatrix} \sim \mathbf{N}_2 \left[\begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 1 & 0.9 \\ 0.9 & 1 \end{pmatrix} \right]$
- MH: a Gaussian jumping rule centered at previous draw.

Be Careful When Combining MH and PCG Sampling

MH within Gibbs Sampler

The *naive* Sampler

What Goes Wrong

The *naive* Sampler:

STEP 1: $\psi_1^{(t)} \sim p(\psi_1)$

STEP 2: $\psi_2^{(t)} \sim \mathcal{M}(\psi_2 | \psi_1^{(t)}, \psi_2^{(t-1)})$ via Metropolis Hastings

The update of ψ_2 depends on both $\psi_1^{(t)}$ and $\psi_2^{(t-1)}$:

- The limiting distribution of the MH step is $p(\psi_2 | \psi_1^{(t)})$.
- If the proposal is rejected, ψ_2 is set to $\psi_2^{(t-1)}$.

BUT: $\psi_1^{(t)} \sim p(\psi_1)$ —independent of $\psi_2^{(t-1)}$ *at every iteration.*

STEP 2 *will never produce samples from* $p(\psi_2 | \psi_1)$.

Two Simple Solutions

Two possible samplers

- 1 A PCG (Simple Collapsed) Gibbs Sampler:

STEP 1: $A^{(t)} \sim p(A)$

STEP 2: Sample $\theta^{(t-1+\ell/L)} \sim \mathcal{M}(\theta|A^{(t)}, \theta^{(t-1)})$
 L times via MH to obtain $\theta^{(t)} \sim p(\theta|A^{(t)})$.

- 2 A pure MH Sampler:

Jumping Rule: $(A^*, \theta^*) \sim p(A^*)\mathcal{M}(\theta^*|A^*, \theta^{(t-1)})$.

Tradeoff: MH is faster, PCG gives independent draws.

PCG has larger expected acceptance probability and lower empirical autocorrelation (compared with L iterations of pure MH).

Multiple Imputation

A simpler solution involves Multiple Imputation:

- Treat m effective areas from calibration sample as “imputations”.
- Fit the model m times in standard way, once with each imputation.
- Compute estimates & errors with *Multiple Imputation Combining Rules*.

$$\hat{\theta} = \frac{1}{M} \sum_{m=1}^M \hat{\theta}_m.$$

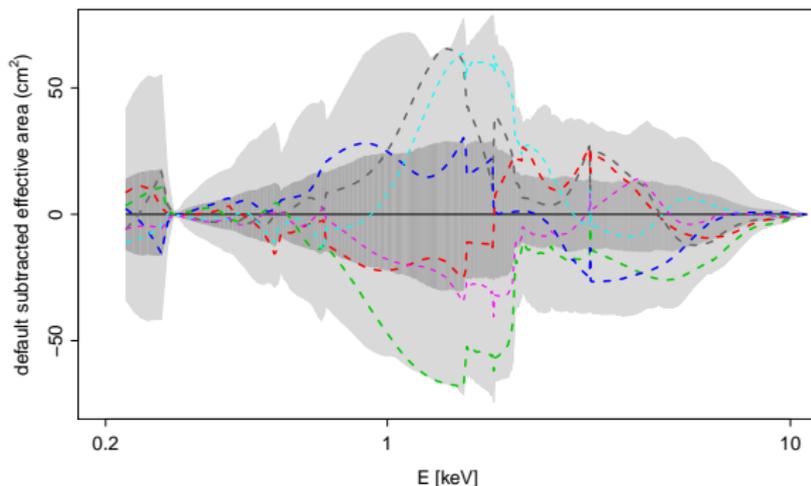

$$W = \frac{1}{M} \sum_{m=1}^M \text{Var}(\hat{\theta}_m), \quad B = \frac{1}{M-1} \sum_{m=1}^M (\hat{\theta}_m - \hat{\theta})(\hat{\theta}_m - \hat{\theta})^\top.$$

$$T = W + \left(1 + \frac{1}{M}\right) B,$$

Approximate Pragmatic Bayes: Replicates of $A \sim p(A)$.

Sticking Point

- We only have a sample from $p(A)$.
- How do we incorporate this sample into our analysis?
- We do not want to store the entire calibration sample.

Simple Emulation of Complex Variability

We use Principal Component Analysis to formulate a degenerate Gaussian approximation to the calibration sample:

$$A \sim A_0 + \bar{\delta} + \sum_{j=1}^m e_j r_j \mathbf{v}_j,$$

A_0 : default effective area,

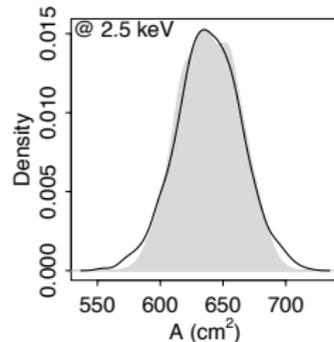

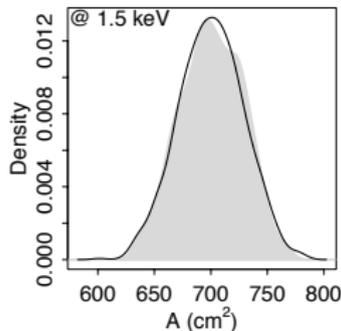

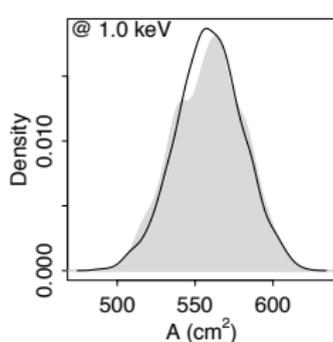

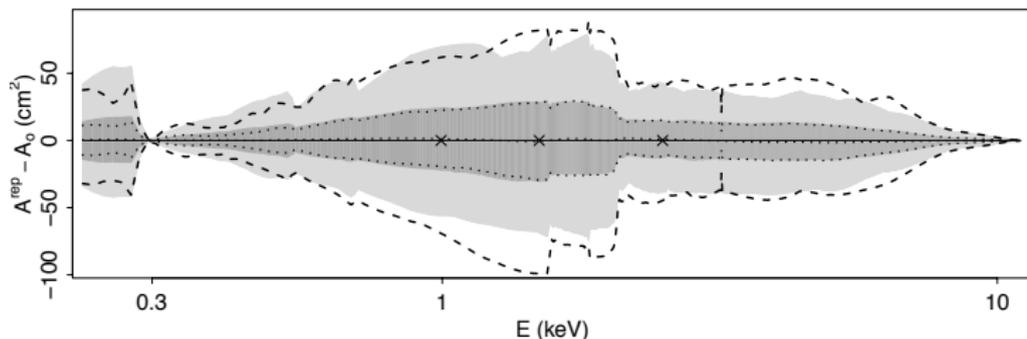

$\bar{\delta}$: mean deviation from A_0 ,

r_j and \mathbf{v}_j : first m principle component eigenvalues & vectors,

e_j : independent standard normal deviations.

Capture 95% of variability with $m = 6 - 9$.

Accounting for Uncertainty

The Two Possible Target Distributions

We consider inference under:

A PRAGMATIC BAYESIAN TARGET: $\pi_0(\mathbf{A}, \theta) = p(\mathbf{A})p(\theta|\mathbf{A}, Y)$.

THE FULLY BAYESIAN POSTERIOR: $\pi(\mathbf{A}, \theta) = p(\mathbf{A}|Y)p(\theta|\mathbf{A}, Y)$.

- MCMC can be used with either target distribution.
- Fully Bayesian computation is more challenging.
- Multiple Imputation gives valid inference under the Pragmatic Bayesian distribution.
- Compare results using simulation studies & data analyses.

The Simulation Studies

Simulated Spectra

- Spectra were sampled using an absorbed power law,

$$f(E_j) = \alpha e^{-N_H \chi(E_j)} E_j^{-\Gamma},$$

accounting for instrumental effects; E_j is the energy of bin j .

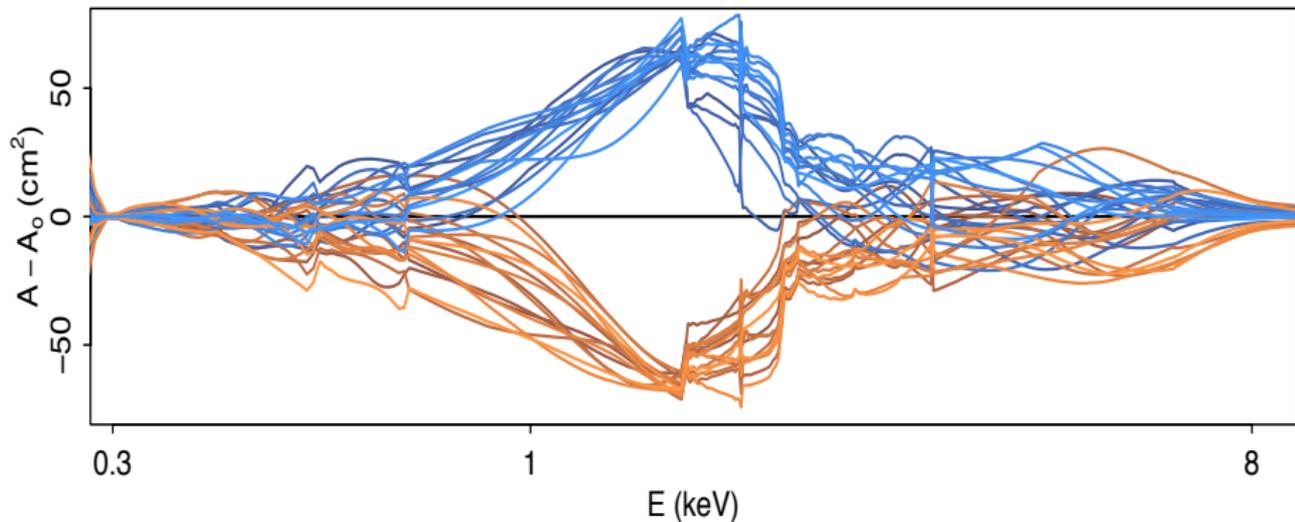

- Parameters (Γ and N_H) and sample size/exposure times:

	Effective Area		Nominal Counts		Spectral Model	
	Default	Extreme	10^5	10^4	Hard [†]	Soft [‡]
SIM 1	X		X		X	
SIM 2	X		X			X
SIM 3	X			X	X	

[†]An absorbed powerlaw with $\Gamma = 2$, $N_H = 10^{23}/\text{cm}^2$

[‡]An absorbed powerlaw with $\Gamma = 1$, $N_H = 10^{21}/\text{cm}^2$

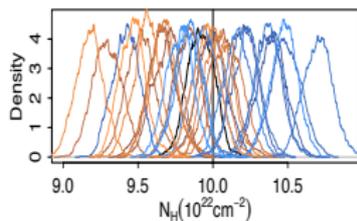

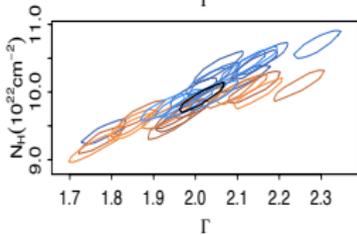

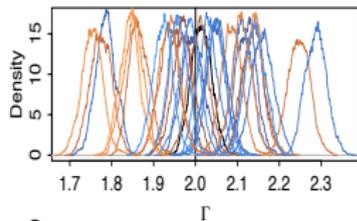

30 Most Extreme Effective Areas in Calibration Sample

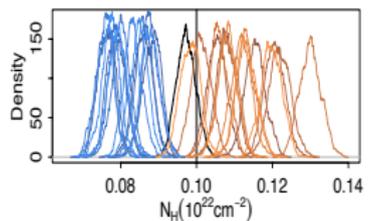

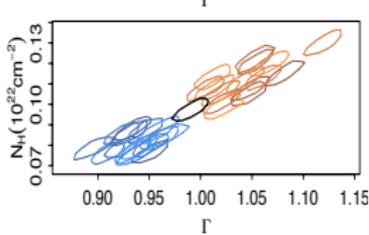

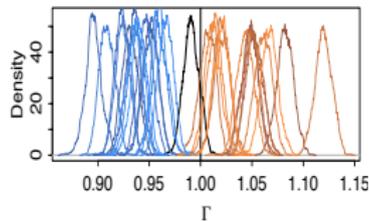

15 largest and 15 smallest determined by maximum value

The Effect of Calibration Uncertainty

SIMULATION 1

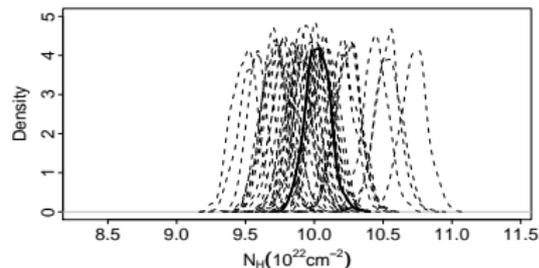

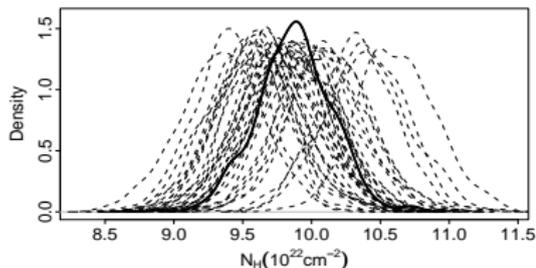

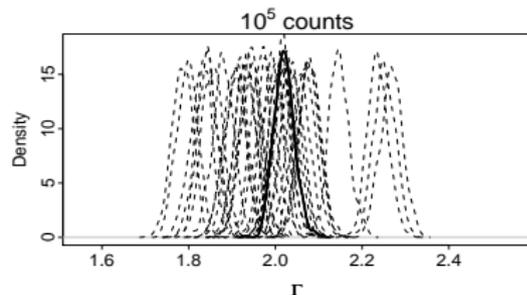

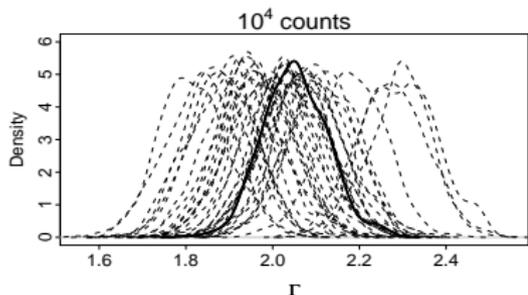

SIMULATION 2

- Columns represent two simulated spectra.
- True parameters are horizontal lines.
- Posterior under default calibration is plotted in black.
- The posterior is highly sensitive to the choice of effective area!

The Effect of Sample Size

The effect of Calibration Uncertainty is more pronounced with larger sample sizes.

Expanded Simulation for Pragmatic Bayes

Simulated Spectra

- Spectra were sampled using an absorbed power law,

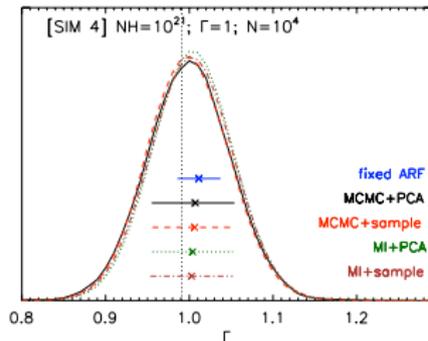

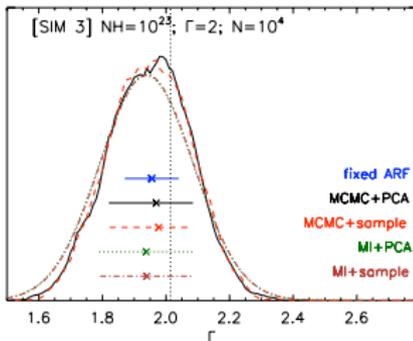

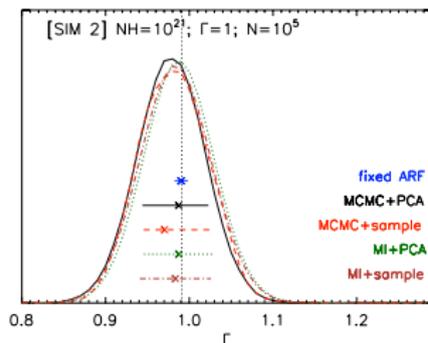

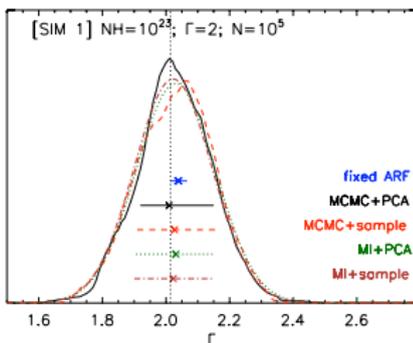

$$f(E_j) = \alpha e^{-N_H \chi(E_j)} E_j^{-\Gamma},$$

	Effective Area		Nominal Counts		Spectral Model	
	Default	Extreme	10^5	10^4	Hard [†]	Soft [‡]
SIMULATION 1	X		X		X	
SIMULATION 2	X		X			X
SIMULATION 3	X			X	X	
SIMULATION 4	X			X		X
SIMULATION 5		X	X		X	
SIMULATION 6		X	X			X
SIMULATION 7		X		X	X	
SIMULATION 8		X		X		X

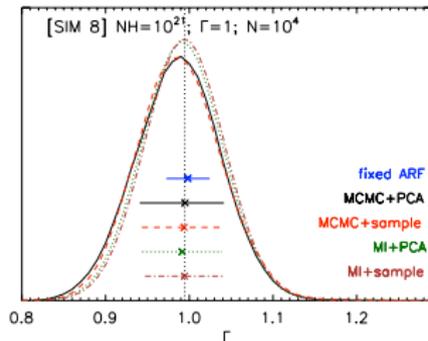

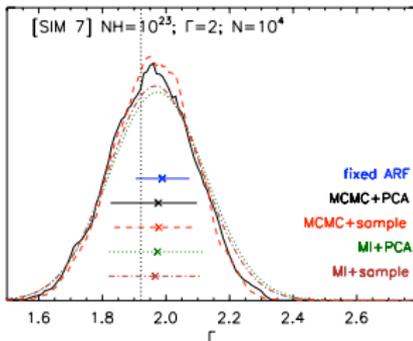

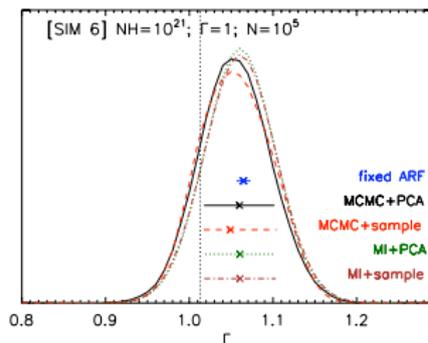

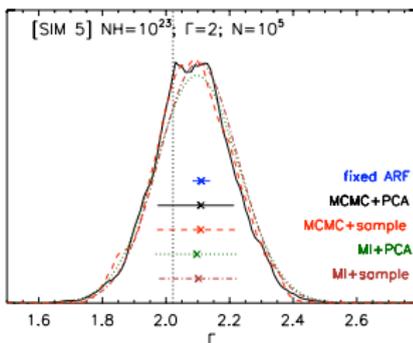

[†]An absorbed powerlaw with $\Gamma = 2$, $N_H = 10^{23}/\text{cm}^2$

[‡]An absorbed powerlaw with $\Gamma = 1$, $N_H = 10^{21}/\text{cm}^2$

Pragmatic Bayes: Higher Variance Than Default

Pragmatic Bayes: Better Coverage Than Default

A Simple Simulation for the Fully Bayesian Sampler

A Simple Simulation.

- Sampled 10^5 counts from a power law spectrum:

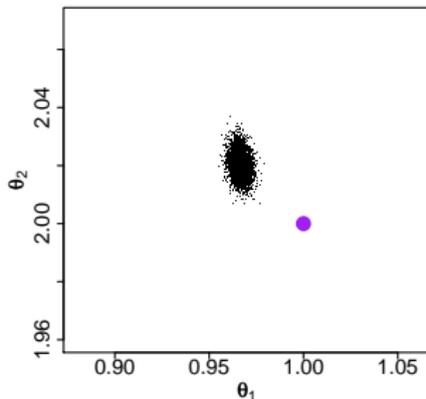

$$f(E_j) = \theta_1 e^{-\theta_3 x(E_j)} E_j^{-\theta_2}$$

- No energy blurring or background contamination.
- Effective area used in the simulation differed from default:

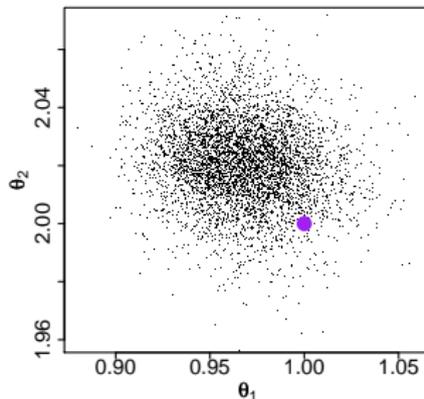

A_{true} is 1.5σ from the center of the calibration sample.

Sampling From the Full Posterior

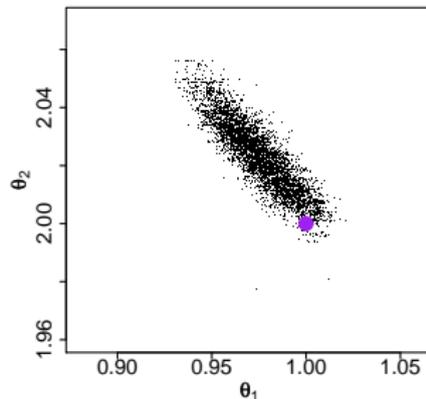

Default Effective Area

Pragmatic Bayes

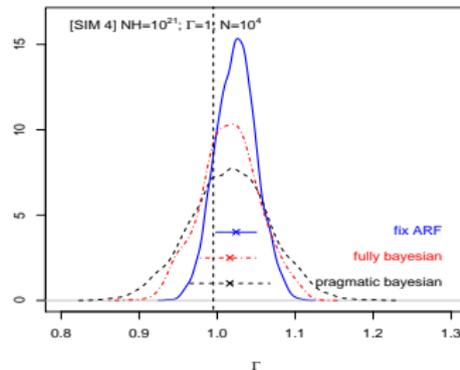

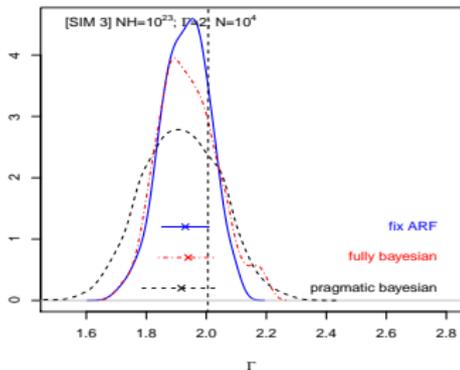

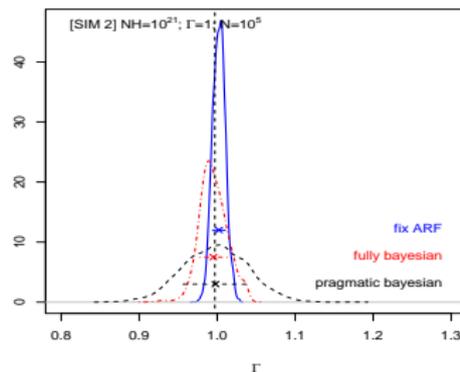

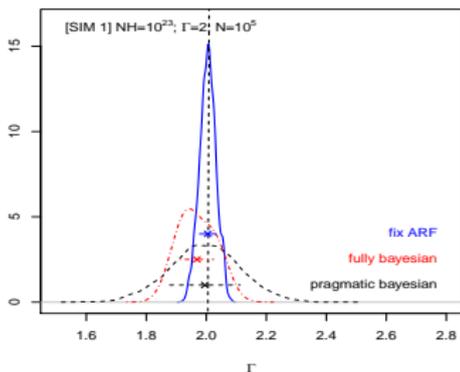

Fully Bayes

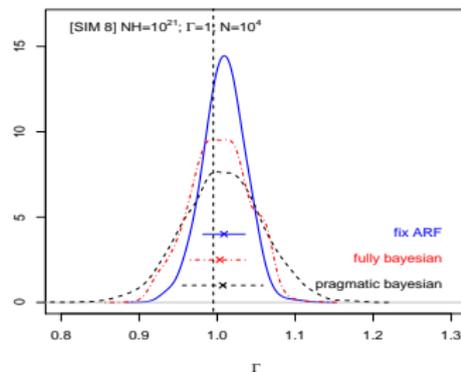

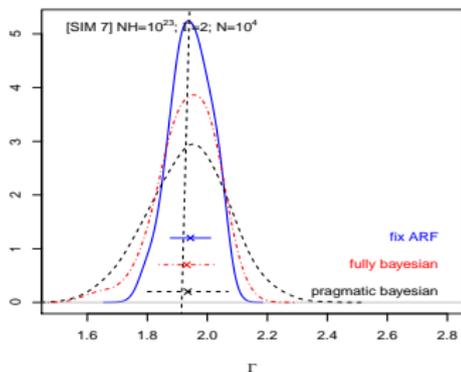

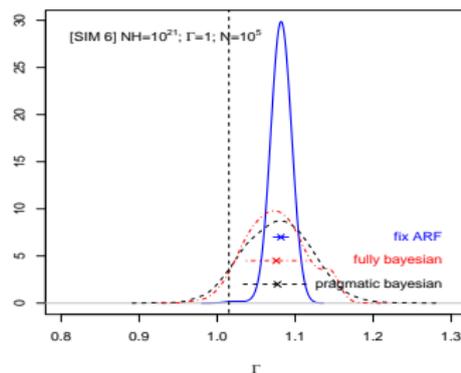

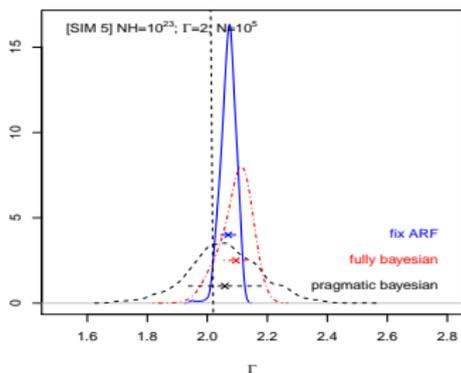

θ_1 = normalization, θ_2 = power law parameter
purple bullet = truth

*Pragmatic Bayes is clearly better than current practice,
but a Fully Bayesian Method is the ultimate goal.*

Fully Bayesian: Less Variance than Pragmatic

Fully Bayesian: Better Coverage than Default

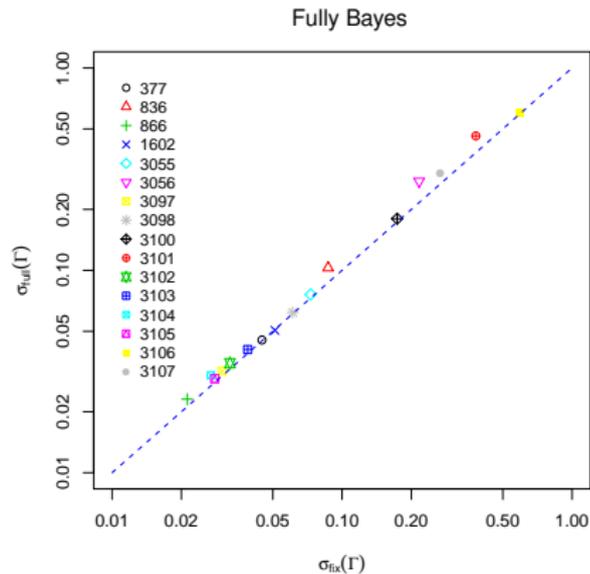

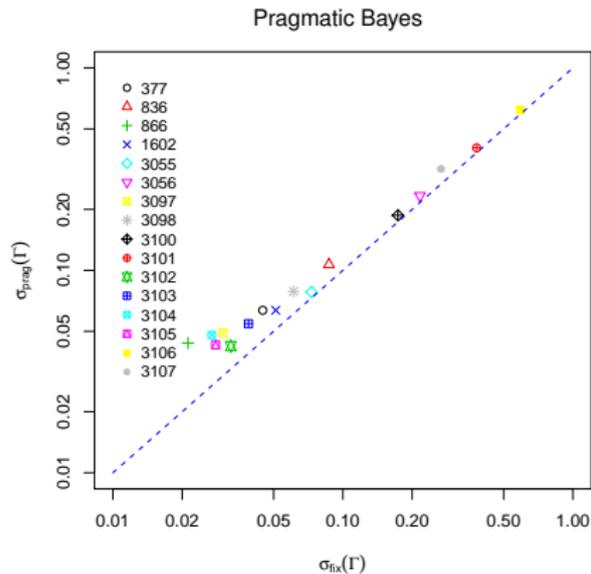

The Effect of Sample Size Redux

A Set of Radio Loud Quasar Spectra

- Pragmatic and Fully Bayesian Methods were applied to a set of Quasars.
- Quasars are among the most distant distinguishable astronomical objects.
- The sixteen Quasar observations varied in size from 20 to over 10,000 photon counts.

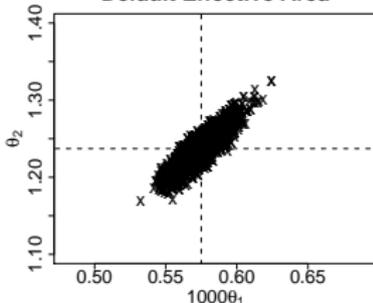

Results

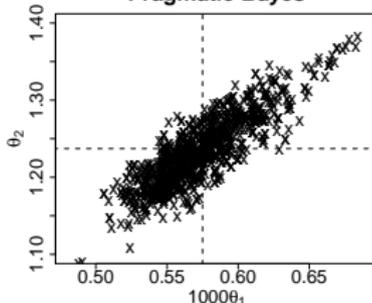

*For large spectra calibration uncertainty swamps statistical error.
 In large spectra fully Bayes identifies A and reduces uncertainty.*
